Notes

What I built

A Laravel + Filament 5 panel over four real entities (Client, Technician, Job, TimeEntry) derived from the three source sheets — not four tables mapped 1:1 to three sheets, since the real Job↔Technician relationship is many-to-many and Client isn't its own sheet at all (see `DATA_MODEL.md`). The import is a single idempotent Artisan command reading the actual `.xlsx` workbook via `maatwebsite/excel` (pinned to a specific commit on its unreleased `4.x` branch — its only stable release line caps out below this project's PHP/Laravel versions; see the README for the detail). All ten data issues in `FINDINGS.md` are handled at import time, not papered over in the UI.

The panel covers everything the brief asked for: a job page showing client, lead technician, every technician's hours, and status; a client's job history; a technician's total hours and work log; an "Outstanding" jobs tab; create/edit forms with validation drawn from what the data actually showed (fixed status/type vocabularies, `J-####` format, completion-after-booking, charge-rate-at-least-cost-rate, and decimal ranges matching each column's actual precision so the database can't reject a save the form already accepted); and — since there was time — a labour-value section on each job comparing the quoted amount against hours × cost rate and hours × charge rate, so the business can see margin per job for the first time.

A second pass went specifically after office usability: labels reworded for a bookkeeper rather than a developer ("Job Number" and "Licence Number" instead of "No"), full-word date formatting (`25 December 2026`), Australian phone numbers normalised and formatted consistently regardless of how they're typed in, click-to-call/copy on phone fields, searchable columns on everything an office user would actually search by, and create/edit forms that return to the list page on save instead of Filament's default of parking you on the record.

What I left out

- **No custom design work** — Filament's default panel styling, per the brief's scope.
- **No Sites entity** — Halden Logistics operates from two addresses under one client; address stays on the Job for now rather than building out a proper site model, since one client isn't enough evidence to justify the extra table yet.
- **No policies/roles** — every authenticated user can do everything, matching "authentication beyond Laravel's default" being out of scope.
- **The two genuine open questions in `FINDINGS.md`** (J. Fitzsimmons' employment status and rate; the actual hours behind the Raman correction entry) are surfaced honestly in the

UI as missing data, not guessed at.

- **Test coverage is targeted, not exhaustive** — one feature test proving the import handles the tricky cases correctly against the real committed workbook (merged technician names, the multi-technician job, the legacy stub job, the self-cancelling correction entry, idempotency on re-run), one unit test for the importer's pure parsing/matching helpers. No panel-level smoke tests — Filament's own CRUD scaffolding is well-tested upstream, so that time went into the import logic, where the real complexity actually lives. Per the brief: "less work finished properly" over broad coverage.
- **No in-panel re-import** — loading a corrected workbook is a CLI command (`sail artisan fairhaven:import`), not a file upload inside the panel. Fine for a developer, not yet for the office.
- **No audit trail** — no record of who changed a rate or a job amount. Worth having before more than one office person uses this day to day, given it's now the source of truth for figures that feed into billing.

What I'd do next

- Send the two open questions from `FINDINGS.md` to the client before building anything further on top of them (a subcontractor rate policy; what actually happened on J-3022).
- If Halden Logistics turns out to be typical rather than an outlier, promote site address to its own entity.
- A "jobs needing a completion date" or "unbilled completed jobs" view — the outstanding-jobs tab covers status, but a completed job with no `Amount` set is a different kind of "not actually finished" that the office would want flagged separately.
- Bulk timesheet entry (a week-at-a-glance grid per technician) instead of one row at a time, since that's closer to how technicians actually described entering their hours.
- An in-panel workbook upload, so re-importing a corrected sheet doesn't need shell access.
- A basic audit trail on `Job` and `TimeEntry`, since both now carry figures that feed into billing.

Time spent

- **Reading and analysing the trial task (30–45 min)** — re-read the brief against the spreadsheet more than once; the "Assigned To isn't the whole story" relationship only became obvious by cross-referencing Jobs against Timesheets row by row, not from the column headings.
- **Backend development — models, migrations, import command (1hr+)** — schema for the four entities, the idempotent `fairhaven:import` command reading the workbook via `maatwebsite/excel`, working through the data issues now written up in `FINDINGS.md`, plus a unit test for the importer's parsing/matching helpers alongside the feature test against the real workbook.

against the real workbook.

- **Frontend development — Filament panel (1hr+)** — built resource by resource: Clients, Technicians, Jobs, Time Entries, plus the relation managers linking them (a client's jobs, a technician's time entries) and the Outstanding-jobs tab and labour-margin view on top.
- **Validation and office-usability pass (30min+)** — form validation matched to the DB column constraints, bookkeeper-facing labels, date/phone formatting, searchable columns, redirect-to-list on save.
- **Write-up — `DATA_MODEL.md`, `FINDINGS.md`, `decisions/`, this file (30min+)**

Total: ***fill in***
